

Advanced Packing Conference (APC)

Flip-Chip Scale Package(FCCSP) Process Characterization and Reliability of Coreless Thin Package with 7nm TSMC Si

E. De Mesa Package Engineer Intel Deutschland GmbH, Munich, Germany

Abstract

Advanced silicon nodes are continuously pushing the cutting edge of assembly technology for coreless thin packages used in mobile and electronic products to allow better power delivery, electrical performance, and higher routing capability. This results in a higher number of I/O and integration flexibilities. Furthermore, integration of a large die size in a smaller package with finer bump and ball pitches, increases the reliability risk. Also, typical mobile applications require stacking a memory die within the package without increasing the total package height. These combinations magnify the stress on back-end-of line (BEOL) stack and bump interconnection-especially on a thin coreless substrate which greatly influence extreme low-K dielectrics (ELK) fragility.

This paper describes the qualification of the 7nm silicon (Si) BEOL stability on thin coreless embedded trace substrate (ETS) with smaller solder ball pitch and a high die to package aspect ratio. In our previous experience, coreless material is generally prone to warpage due to absence of the core that supports the package rigidity. Therefore, controlling and minimizing warpage at room and elevated temperature is crucial, as the stress propagates into the BEOL, resulting in a significant impact on the chip reliability, especially for ELK structures. Simulation of thermal and mechanical stress in Finite Element Modeling (FEM) was completed to confirm warpage behavior. Shadow Moiré was documented under temperature loading and package coplanarity empirical data was collected.

Within the development phase, the package warpage was successfully reduced and coplanarity on thin coreless substrate was within specification. Significant improvement is attributed to mold compound higher coefficient of thermal expansion (CTE) and lower elastic modulus. Multiple reliability tests in accordance with JEDEC standard was conducted. Results confirmed the BEOL stack integrity and all related tests passed.

Philippines. Currently, working under Technology Enablement Group engaged in advanced package development at Intel Deutschland Gmbh.

Active Mold Packaging for novel Antenna-in-Package interconnection and manufacturing

F. Roick Business Development Active Mold Packaging LPKF Laser & Electronics AG, Garbsen, Germany

Abstract

IC package designers wishing to benefit from space saving Antenna-in-Package (AiP) technologies rely on an intricate selection of materials and interconnect processes to produce a self-contained integrated module. This paper presents a new way to reduce the production complexities of AIP by introducing a novel homogeneous packaging technology: Active Mold Packaging (AMP).

Active Mold Packaging directly establishes electrical connections, such as patch antennas, signal vias, and Electro-Magnetic-Interference (EMI) shields for RF applications on the surface and in the volume of the encapsulating Epoxy Mold Compound (EMC). Advancing the development of multifunctional compact devices, AMP in essence transforms the passive and undeveloped real-estate of the EMC into an active carrier of package functionality.

A 2.5D interconnect technology to simplify AiP designs and EMI shielding will be presented. AMP integrates familiar process steps: molding of EMCs, Laser Direct Structuring and direct electro-less and galvanic plating. In combination the processing steps result in a robust scalable manufacturing solution, AMP. AMP is uniquely suited for the production of AiP but also a foundation design platform for other novel IC packages. Critical process attributes of AMP are discussed and used to propose a commercial AMP-AiP model. Measuring the influence of key design elements of an AMP fabricated EMC micro strip antenna and EMI shield within the 5G radio frequencies; sub-6GHZ, mm-wave, and beyond 5G (« B5G ») ISM bands yields strategies for implementing the AMP technology. Consideration is granted to the impact of the LDS activator, the laser structuring parameters, and electroless plating factors on the model devices. Lastly, the proposed commercialization of the AMP-AiP is modelled through a cost-model comparison.

Biography

M. Sc. Florian Roick, Business Development Manager Active Mold Packaging

Born in 1981. He holds a degree as Bachelor of Science in Applied Physics from Dublin Institute of Technology. And a degree as Master of Science in Electrical Engineering with focus on laser systems, laser physics and microsystems engineering from Hochschule Bremen.

Since 2006 employed at LPKF Laser & Electronics AG, until 2008 as application engineer for the StencilLaser business unit. Between 2008 and 2019 strategic product manager responsible for aligning the product portfolio with the needs and requirements of the PCB and SMT markets.

Since 2019 Business Development Manager for LPKF's Active Mold Packaging technology. That is to electrically functionalize the real-estate of the epoxy mold compound on the base of LPKF's patented Laser Direct Structuring (LDS) technology.

Co-inventor of the parametric stick-in and co-author of a variety of publications.

High throughput & high yield heterogeneous integration with implemented metrology for collective D2W Bonding

E. Brandl Business Development Manager EVG, St Florian am Inn, Austria

Abstract

Heterogeneous integration offers several advantages in performance gain, functionality increase as well as yield enhancement. Depending on the device architecture and level of integration, several integration methods at different manufacturing levels can be used to create heterogeneous integrated systems. Processing on die level is often practiced, leading in some cases to throughput and yield considerations. Collective die to wafer bonding can enable several integration processes on wafer level via using a reconstituted transfer carrier approach. Especially in hybrid and fusion bonding this method enables heterogeneous integration as processes such as plasma activation are better performed on wafer level for high throughput.

As for all semiconductor processes, collective die to wafer bonding demands suited and optimized measurement solutions for process monitoring and yield optimization. Fitting metrology combined with a feedback loop for production equipment is essential to increase yield of the whole integration process and an important factor in successful heterogeneous integration. Regarding metrology implementation, two scenarios are generally possible. One is the implementation of metrology within the bond equipment, which allows a quick reaction and the process parameters can be directly adjusted. The consideration of such implementation demands throughput matching for high equipment efficiency. The other implementation method is an external metrology tool, where the feedback is delayed, but on the other hand one metrology tool can serve several production tools.

In the presentation the process flow of collective die to wafer bonding will be discussed in more detail as well as the advantages and disadvantages of the two metrology implementation scenarios.

Biography

Elisabeth Brandl received her master in technical physics from the Johannes Kepler University Linz, Austria in Semiconductor and Solid State Physics. Since 2014, she has been responsible for Product Marketing Management for temporary bonding and metrology at EVG.

Vertical stacking of controller IC on a copper clip attached on MOSFET as a space-saving solution for high current switch e-fuse applications

A. Attard Sr. Technical Program Manager & Assembly Business Development United Test and Assembly Center Ltd, Singapore, Singapore

Abstract

Recently there has been an increasing demand for high-performance computing, mainly driven by data centers, online storage, cloud-based servers, and online software services. These applications require high computing power which drives high energy consumption, so the power systems employed need to run at extremely high efficiency and have small form factors, whilst offering very high reliability and minimal thermal losses during their deployment. This can be achieved by improving both the power semiconductor device technology, as well as the power packaging technology, such that maximum power performance and reliability can be extracted from the PCB area available.

Power MOSFET technology has evolved to reduce switching losses and allow high frequency switching. Power modules have also been developed to integrate MOSFET dies together with a controller IC in a single package to offer a small form factor solution. From an interconnect perspective, copper clip bonding began to replace wire bonding technology due to the lower resistance and parasitic inductances it offers compared to wire bonding. Whereas most multi-die power module packages employ a side-by-side die configuration due to the wire bonding interconnect method, copper clip packages allow for vertical die stacking, which results in a smaller package for the same power rating.

In this paper, we propose a QFN power module package solution for an electronic fuse (e-fuse) device in high-performance computing applications, comprised of a controller IC vertically stacked onto the copper clip used to create the interconnect between the MOSFET die and the lead frame. This approach provides a vertically integrated power module solution, offering a significantly reduced form factor versus a side-by-side power module approach or the use of two separate QFN packages for each die. Typical e-fuse applications need two separate QFN packages, for example, a 3mm x 3mm QFN for the controller IC and a 5mm x 6mm QFN for the MOSFET die, occupying a total of 39mm² of PCB area. Comparatively, a vertically stacked power module can be packaged in a 5mm x 5mm QFN occupying a total PCB area of 25mm², resulting in 36% less PCB area usage. The vertically stacked power module also offers excellent thermal performance despite the increased power density of the package. Thermal simulations performed using a 5mm x 6mm e-fuse package structure with 4.1W of combined power dissipation show that a Theta Ja of 25.3 °C/W and maximum temperatures of around 128.8°C for the IC and 123.9°C for the MOSFET are achieved under still air conditions.

The assembly process flow will also be discussed in more detail, with focus on critical process steps such as vacuum reflow to ensure minimum voiding in the solder interconnects between MOSFET and lead frame, and copper clip and MOSFET. Examples of actual devices will also be shown. UTAC's outlook on more advanced power modules will also be shared, showing proposals for packages with increased complexity using three dies and copper clips in a vertically stacked configuration for smart power stage applications with reduced footprint requirements.

Biography

Alastair Attard is Senior Technical Program Manager and Assembly Business Development at UTAC Group. He has a Bachelor's degree in Mechanical Engineering and an Executive MBA from the University of Malta. He has over 14 years of experience in the assembly & test of semiconductor devices.

Prior to joining UTAC, Alastair worked at STMicroelectronics Malta from 2006 until 2011, first as a Process Engineer on flip chip assembly for SiP and later as a Package Development Senior Engineer for SiP and MEMS packages. He later joined Besi in 2011, where he was Manager of the Process Development group until 2018.

At UTAC, he is responsible for Technical Program Management and Assembly Business Development in the European region, with main focus on Automotive, Industrial, SiP, Power and MEMS areas.

New solutions for plasma dicing, and new solutions for processing of SiC wafers ranging from ingot splitting, grinding, polishing to high speed and chipping free dicing.

G. Klug General Sales Manager DISCO Hi-Tec Europe GmbH, Sales, Kirchheim b Muenchen, Germany

Abstract

Wafer thinning (Kezuru and Migaku) and dicing (Kiru) is essential for advanced packaging, for achieving narrow street widths and for making thin dies for 3D-packaging. New solutions on plasma dicing in combination with latest tapes and grinding technology enable the supply of perfect top side, back side and side wall quality on dies in thickness range from $20 - 150 \mu m$.

Plasma dicing has various advantages comparing to the conventional dicing. However, during the plasma dicing process the sensitive wafer front can be at risk due to the surface being exposed to plasma gas. It is common to protect the wafer front surface by photoresist in the wafer fab, which increases the cost and the processing steps.

DISCO has developed a special surface protection film and a total new processing flow for plasma dicing to overcome these issues.

SiC is getting more and more important for the energy efficient devices. Since SiC is a very expensive material DISCO focuses on technologies for gaining as many as possible wafers and dies of outstanding quality out of it.

SiC ingot splitting by KABRA:

KABRA is a new method for SiC-ingot slicing by using a laser instead of a wire saw. In this process, a special layer is made inside of the ingot by laser irradiation and then the wafer is split from the ingot. 40% more wafers are obtained out of one ingot compared to conventional method.

SiC ingot and wafer grinding and polishing:

After splitting the wafer from the ingot, the ingot side and the wafer side need to be ground and polished. DISCO has developed grinding wheels and polishing pads (E Pad) suitable for wafer manufactures and device makers.

SiC wafer dicing by blade or laser:

To obtain more numbers of dies from a wafer, cutting streets can be reduced down to 50 µm and less. With our special technologies cutting speed and quality have been greatly improved, too.

Biography

Gerald Klug has studied business-engineering at the University of Siegen and graduated as Diplom-Engineer in 1998.

He started his carrier as a designer and project engineer of steel cutting lines at a globally leading German machine manufacturing company.

At the end of 2000, he joined DISCO as Sales Engineer. Meanwhile he has been working for DISCO for 19 years and is nowadays operating as General Sales Manager for the territory of Europe.

Virtual Prototyping for System-in-Package with Heterogeneous Integration - Enabler for faster Time-to-Market

G. Gadhiya Research Associate Fraunhofer ENAS, Chemnitz, Germany

Abstract

Heterogeneous Integration in System-in-Package (SiP) based on Fan-Out Wafer Level Technologies allows to meet various requirements such as improved performance, smaller form-factor, functional safety and low cost for upcoming new applications. Due to the thermo-mechanical stresses leading to device failure, the reliability risks must be assessed during the development of new products aiming for a design optimized for reliability. Virtual Prototyping (VP) based on Finite Element (FE) simulation allows the analysis of the thermo-mechanical situation during fabrication, tests and service within short time, allowing shorter development time. However, it requires parametric FE models, precise material and experimental data for validation. Because of this initial investment, it is advised to develop the VP schemes in a way that they are able to cover a wide variety of future products.

The talk will present a modular system of parametric FE models that enables virtual reliability assessments of various SiP products based on Fan-Out Technologies such as WLSiP, eWLB-PoP, RCP, InFO, FOPLP, WFOP, SiWLP and SWIFT-PoP [1][2]. By combination of common packaging components like die, mold, redistribution layers, solder balls, vias, integrated passives, and boards from the library of pre-calibrated parametric FE models in ANSYS, digital twins of a large number of individual package configurations can readily be generated, e.g. 2D, 2.5D and 3D/PoP. The talk highlights the flexibility of the modular system of parametric FE models by four very different industrial packages: Radar sensor, Silicon photomultiplier, Automotive inertial sensor and Camera module. The VP scheme for a new pad design of a multi-chip SiP sensor is demonstrated in detail to show the great support that virtual optimization and qualification schemes can provide. They can reduce Time-to-Market of new SiP products by 50%-75%.

Ghanshyam Gadhiya received his M.Sc. degree in Micro and Nano Systems, with a specialization in Finite element analysis of power module from Technical university of Chemnitz in 2013. Since 2014, he is working as a scientific researcher at the Micro materials center, Fraunhofer ENAS. His main research focus includes parametric finite element modelling, thermo-mechanical simulation and optimization of microelectronics packages using FE-program ANSYS. He has been also involved with several industrial projects for residual stress, humidity and vibrational analysis. His current research interests include fan-out wafer level packaging technology, system-in-package, virtual prototyping and micro-electronics failure analysis.

Innovative Packaging and Evaluation Approach for an Universal Sensor Platform

C. Brockmann Group Manager Sensor Nodes and Embedded Microsystems Fraunhofer Institut für Zuverlässigkeit und Mikrointegration, RF& Smart Sensor Systems, Berlin, Germany

Abstract

This article presents an innovative packaging and evaluation approach for a newly developed Universal Sensor Platform (USEP) based on a system in package RISC-V integrated microcontroller with a top-level functionalized system in package design. Specific functions of the sensor platform are assigned to four different physical levels in the whole integration concept. The technical implementation of the functional requirements requires innovative, technological solutions in the packaging and interconnection technology (AVT) but also new approaches for testing methods and infrastructure across the different levels. Starting from a bare die, inclusion of package co-design, new assembly and interconnection techniques, up to the provision of the evaluation and testing of the platform system, the increasing complexity of this research projects in microelectronics becomes apparent.

In the final step of finalizing the system in package solution, the sensors are applied to the functionalized package surface. This enables the system to directly measure various parameters such as temperature, humidity and pressure. The electrical connection of the components is done on a multilayer redistribution layer, which is applied to the mold material of the package and connected to the underlying system core with through package vias. For testing, a modular evaluation board is available, which allows the connection of an FPGA-based emulation environment. Furthermore, various test adapters can be connected to the data bus, thus significantly increasing the modular testability. A test socket detachable from the circuit board connects the manufactured modules with their 256-BGA footprint with all electrical operation and debug signals and plays a central role for the actual chip test because it enables short testing and configuration cycles.

Biography

Carsten Brockmann studied Technische Informatik at the Technical University of Berlin and received his diploma in 2008. He worked as a scientist at the Forschungsschwerpunkt Technologien der Mikroperipherik in the field of wireless sensor nodes until 2014 when he changed to Fraunhofer Institute for Reliability and Microintegration. In different national and international research projects he proceeded with his research work and became the group manager for sensor nodes and embedded microsystems in 2015.

Enabling Assembly and Packaging Material Developments for Next Gen RF Devices, Antennas and Radars

R. de Wit Business Development Manager EMEA Henkel Belgium NV, Westerlo, Belgium

Abstract

Smart Electronics' market trends like 5G Telecom and Autonomous Driving are leading advanced semiconductor packaging innovations towards higher functionality, enhanced connectivity at higher frequencies, RF signal interference isolation (shielding), smaller form factors (miniaturization) and reduced power consumption. To meet these demands, semiconductor package designs continue to evolve towards MULTIPLE DIE using System-in-Package and Wafer Level architectures. Especially for next generation RF devices, antennas and radars, the thermo-mechanical, thermal resistance and (di)electric properties of the assembly and packaging materials play a key role as well as fast and low temperature processing/curing. This presentation will give an overview of the challenges and solutions from a semiconductor packaging material perspective based on recent customer experiences and ongoing developments to enable new designs. The focus will be on thermal performance of different die and lid attach assembly methods and thermal interface materials, EMI shielding effectiveness of thin silver layers, dielectric constant and loss factors of liquid wafer level encapsulants and underfills at 28-50 GHz and above, etc.

Biography

Ruud de Wit is responsible for managing Henkel's Semiconductor, Sensor & Consumer Electronics Assembly Materials business development within EMEA region. Ruud has a BSc degree in Mechanical Engineering followed by several polymer, sales and marketing courses. Ruud is working for Henkel since 1990 in multiple positions including technical customer support, quality assurance and engineering, and global semiconductor account and product management.

Development of a foil based flexible interposer for power conditioning IC in energy autarkic systems

E. Yacoub-George Scientist

Fraunhofer EMFT, Flex, Munich, Germany

Abstract

The EU ECSEL project EnSO aims the development of autonomous micro energy sources (AMES) for innovative electronic devices that target key applications such as smart health, smart mobility and smart society. An AMES provides energy for sensors, data processing and data transmission and consists of micro storage element, energy harvester, smart charger and power conditioning IC. Smart integration of these building blocks to fabricate an AMES with an appropriate form factor was a key objective in the EnSO project.

Although in printed electronics, the PCB board is ususally fabricated with an innovative technology it is often still assembled with bulky and rigid SMD components. In such a case, some of the primary advantages such as conformability and flexibility that are commonly attributed to printed electronics are lost. In order to overcome this limitation, we developed a new package type called "flexible interposer". It consists of a Cu wiring film fabricated in roll to roll, a thinned IC and a flexible polymeric mould cover. The interposer is designed with a QFN format and is characterized by a reduced thickness and some mechanical flexibility. The flexible interposer approach was developed and characterized for a daisychain chip and a commercial power conditioning IC of the latest generation from STMicroelectronics. The fabrication process was established with the daisychain chip to facilitate electrical characterization and reliability testing and was then adapted for the STBC15 IC. 30 interposer samples have been prepared and characterized. The obtained process yield indicates a robust fabrication process. Since all process steps are compatible with roll to roll production, we expect a high potential for up-scaling that offers the chance to close the gap between research and market.

The research results were obtained in the scope of EnSO project that has received funding from 1) EU under Grant Agreement no. 692482 and 2) BMBF with National Grant no. 16ESE0088.

Biography

Erwin Yacoub-George received his Ph. D in Chemistry (1994) at Technical University of Munich where he developed a production process for polysiloxane beads. Since 1994 he worked for the Fraunhofer Society in Munich. He started his research works on the development of optical biosensor systems. In 2002 he joined the flexible electronics team and developed self-assembly processes for thinned ICs as well as heterogeneous integration techniques for printed and large area electronics. He is currently working as a project manager on European and National research projects with a focus on thin chip integration in flexible foil substrates.

Auxetic Liquid Crystal Elastomers – A Novel Underfill Resin Solution

Director University of Leeds, School of Physics and Astronomy, Leeds, United Kingdom

Abstract Auxetic Liquid Crystal Elastomers – A Novel Underfill Resin Solution

Authors : H F Gleeson, M Hussain, P J Hine, E I L Jull, R Mandle, School of Physics and Astronomy, University of Leeds, United Kingdom and K Rollins, Welbury Consulting Ltd, Northallerton, United Kingdom

This paper will describe the use of a recently (2018) discovered novel class of materials – auxetic liquid crystal elastomers (LCEs) – which offer the potential to provide significant performance enhancements over conventional flip and chip underfill resin solutions. An auxetic material exhibits a negative Poisson's ratio – it becomes thicker (rather than thinner) under strain. LCEs offer auxetic behaviour at a molecular level, a significant advantage over structural auxetics that are limited to size regimes of 10-100mm. The auxetic LCE materials are characterised by their ability to provide improved impact resistance and delamination performance when placed under stress which will enable their use in a wide range of applications – body armour, safety glass and chip packaging underfill solutions being but three examples. This level of performance improvement is obtained by design at the molecular level and therefore provides a level of "tunability" which will allow the materials to be utilised in a wide range of device architectures and underfill formulations. The reactive nature of the materials when placed under stress is illustrated in this graphic :-

(Graphic could not be uploaded - could support be provided to make this happen?)

This ability of auxetic LCE materials to absorb shock (mechanical and thermal) in this manner will provide an outstanding level of protection between chip, board and solder materials. It is anticipated that this will translate into wider design flexibility and robustness and in doing so contribute to improved device performance windows. The paper will provide the full materials inventory of performance specifications comparing the materials with incumbent solutions.

Biography

Dr Rollins spent his industrial career in the ICI, DuPont and DuPont Teijin Films Polyester Films businesses. A significant proportion of this experience was in the Displays, Electronics and Flexible Electronics industries. During this time he was a two term Chairman of the SEMI FlexTech industry association. He is presently working with the University of Leeds, focused on the commercialisation of novel auxetic liquid crystal elastomer materials which are the subject of this paper.

Holistic thermal material characterization approach for thermal performance optimization of electronic packages

T. von Essen Head Of Marketing Berliner Nanotest und Design GmbH, Berlin, Germany

Abstract

Thermal management is a key component of electronic package design in general and heterogeneously integrated System-in-Package design in specific. Functionality, life expectancy and reliability of packages strongly depend on their thermal performance. The application of the right materials is most important to achieve the targets. Furthermore, numerical analysis for lifetime prediction requires correct material data for credible propositions.

As material properties strongly depend on use case and field scenario, but material datasheets, unfortunately, tend not to provide the details and accuracy required, it is crucial to acquire material data reliably using suitable methods.

The presentation will describe a systematic approach to identify the contribution of different materials in electronic packages to the overall thermal performance and which ones are potential bottlenecks. For the different material classes, different characterization methods are presented and discussed.

Thermal interface materials (TIMs) are centerpiece of the discussion, as they contribute with up to two thirds to the overall thermal junction to case resistance. The best approach to TIM characterization is following the ASTM D 5470 guideline, which does not only provide thermal conductivity as output but also the interface resistance, which is a crucial component of thermal interfaces with continuously shrinking gap width. Second important group of materials in the list are metals and semiconductors in the package, all with rather high thermal conductivity and not possible to characterize using the ASTM D 5470 approach. However, a quite similar approach, moving from through-plane to in-plane measurement, will be presented. It allows the precise characterization of such materials and yields thermal conductivity and diffusivity as result, which is gratefully acknowledged input to numerical analysis. The same methodological approach enables the characterization of metal-based die attach materials such as solder and sintered material samples. Eventually, a system-level evaluation method will be shown that can provide performance benchmarking of assembled prototypes and can greatly serve as validation beacon for numerical models.

In conclusion, an example of a typical electronic package will be shown, summarizing all presented methods and system-level test. The used complete off-the-shelve product family offering all the presented methods ready to use will be introduced.

Biography

Tobias von Essen studied Micro Systems Engineering and Systems Engineering at the University of Applied Sciences in Berlin, receiving his master's degree in 2013, where he implemented a test stand for transient thermal characterization. Since 2011, he is part of the Nanotest team, first as student worker and, subsequent to his master's thesis, as permanent employee. Tobias is responsible for marketing and sales activity at Nanotest, but also leads multiple software projects of Nanotest-proprietary characterization systems and partakes in method and system development. His scientific focus is steady-state thermal material characterization.
